Inside Earth Webquest Answers: Detailed Breakdown

Below are comprehensive answers to the typical questions found in the Inside Earth Webquest, organized by section.

1. Describe the Earth's layers and their characteristics.

Answer:

Earth's interior is structured into four main layers:

- Crust: The outermost layer, solid and relatively thin compared to other layers. It varies in thickness from about 5 km (oceanic crust) to 70 km (continental crust). Composed mainly of silicate rocks, it is where we live and where most geological activity occurs.

- Mantle: Located beneath the crust, extending to about 2,900 km below the surface. It is semi-solid but behaves plastically over geological time scales. Composed mainly of silicate minerals

rich in magnesium and iron, the mantle is responsible for convection currents that drive plate movement.

- Outer Core: A liquid layer about 2,200 km thick, composed mainly of iron and nickel. The movement of liquid metal generates Earth's magnetic field.

- Inner Core: The innermost layer, solid and about 1,220 km thick, composed primarily of iron and nickel. Despite the high temperature, pressure keeps it in a solid state.

2. How do seismic waves help scientists understand Earth's interior?

Answer:

Seismic waves, generated by earthquakes or artificial sources, travel through Earth's interior and are recorded by seismometers. There are two main types:

- P-waves (Primary or compressional waves): Travel through solids, liquids, and gases. They are the fastest seismic waves and arrive first at seismic stations.

- S-waves (Secondary or shear waves): Travel only through solids and arrive after P-waves.

By analyzing how seismic waves change speed, direction, or are blocked, scientists determine the properties and boundaries of Earth's layers. For instance, the fact that S-waves do not pass through the outer core indicates it is liquid.

3. What evidence supports the existence of Earth's layers?

Answer:

Key evidence includes:

- Seismic Data: Variations in wave speed and the presence of shadow zones support layered structure.

- Magnetic Field: The Earth's magnetic field, generated by the liquid outer core, confirms its existence.

- Gravity Measurements: Variations in Earth's gravity suggest density differences among layers.

- Mineral Studies: Laboratory experiments on rocks under high pressure simulate conditions in Earth's interior.
- Volcanic Activity: The eruption of magma from deep within Earth provides clues about its composition.

4. Explain the process of plate tectonics and how it causes geological activity.

Answer:

Plate tectonics is the scientific theory describing the movement of Earth's lithospheric plates. These plates are large fragments that cover Earth's surface and float on the semi-fluid mantle.

Key processes include:

- Divergent Boundaries: Plates move away from each other, creating new crust (e.g., mid-ocean ridges).
- Convergent Boundaries: Plates move toward each other, causing mountain formation, subduction, and earthquakes.
- Transform Boundaries: Plates slide past each other horizontally, leading to strike-slip faults and earthquakes.

This movement results in:

- Earthquakes
- Volcanic eruptions
- Mountain building
- Ocean basin formation
